Biography Verner was born in New York City, the son of actor H. D. Verner. In 1885 he made his first stage appearance in The Masquerader, a musical play written by H. D. Verner. Verner appeared in a great many Broadway productions including Heir at Law, The Fortune Hunter, and The Duchess of Buffalo. During his career, he was a member of the stock company of many New York theatres, including the Palace Theatre, the Broad Street Theatre, the Empire Theatre, the Rialto Theatre, and the Shubert Theatre. Verner also appeared in motion pictures, particularly Westerns, and on television during the early to mid 20th century. His television appearances include: The Cisco Kid (1940 episode, "The Badge of Cain") The Lone Ranger (1951 episode, "The Shadow Riders") The Adventures of Kit Carson (1951 episode, "The Mystery of the Towering Rock") He died in New York City in 1956. Partial filmography The Untamed (1914) The Scarlet Angel (1915) The

The quantum dots are solid particles composed of a lattice of atoms with a band gap energy. Recently, a quantum dot electroluminescent device (also referred to as a quantum dot light-emitting diode) has been developed, which converts a current into light through the quantum dots. The quantum dot electroluminescent device exhibits the advantages of high brightness, a high response speed, and the like, when compared with other types of organic light-emitting devices and organic electroluminescent devices. Currently, a quantum dot electroluminescent device includes a substrate, an anode electrode (a first electrode), a hole transport layer (an organic semiconductor layer), a light-emitting layer, an electron transport layer (an organic semiconductor layer), and a cathode electrode (a second electrode), in that order. The hole transport layer and the electron transport layer function as an electron injection layer and a hole injection layer, respectively. In such a quantum dot electroluminescent device, the light-emitting layer is interposed between the hole transport layer and the electron transport layer. The performance of the organic semiconductor layers, such as the hole transport layer and the electron transport layer, is greatly influenced by the number of interface states of the semiconductor quantum dots. Accordingly, it is desirable to form thin films having low interface states so as to achieve high performance. The formation of the thin films having low interface states can be achieved by introducing a material having high reactivity into the system and by preventing impurities from diffusing to the interface during the formation of the thin films, thereby reducing the number of interface states of the semic 2d92ce491b
